# Newton Raphson Full Model

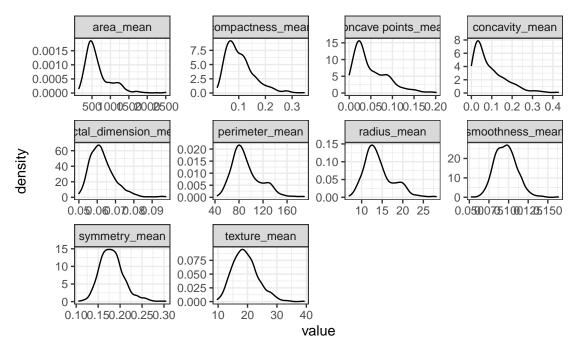

Waveley Qiu (wq2162)

2022-03-22

#### EDA

Let's import and take a look at the data.

Let's take a look at the distributions of other variables.

tbl\_summary(bc, by = diagnosis)

We want our outcome variable to be binary. Let's create a new outcome variable, y, which will be 1 if diagnosis == 'M' and 0 if 'diagnosis == 'B'.

```
bc <- bc %>% mutate(y = ifelse(diagnosis == "M", 1, 0)) %>% relocate(y)
```

# **Multicollinearity Investigation**

Let's look at the correlations for all predictors.

```
corr_cross(bc_corr, # name of dataset
  top = 25 # display top 10 couples of variables (by correlation coefficient)
) +
  geom_text(aes(label = round(corr,3)), hjust = 1.3) +
  labs(title = "Figure 2: Ranked Cross-Correlations")
```

Yikes. Let's make some cuts  $(r^2 > 0.9)$  and reevaluate. To begin, we zoom in on our culprits.

```
# call correlation matrix
corr_df <- cor(bc %>% select(-c(diagnosis)))

# convert matrix to tidy data frame and restrict to highly correlated pairs
corr_df <-
    data.frame(
    v1 = rownames(corr_df)[row(corr_df)[upper.tri(corr_df)]]
    , v2 = colnames(corr_df)[col(corr_df)[upper.tri(corr_df)]]
    , corr = corr_df[upper.tri(corr_df)]
    ) %>%
    arrange(-abs(corr)) %>%
    filter(abs(corr) > 0.90)
# output results
corr_df %>% knitr::kable()
```

v1	v2	corr
radius_mean	perimeter_mean	0.9978553
radius_worst	perimeter_worst	0.9937079
radius mean	area mean	0.9873572
perimeter_mean	area mean	0.9865068
radius_worst	area worst	0.9840146
perimeter_worst	area worst	0.9775781
radius_se	perimeter_se	0.9727937
perimeter_mean	perimeter_worst	0.9703869
radius_mean	radius_worst	0.9695390
perimeter_mean	radius_worst	0.9694764
radius mean	perimeter_worst	0.9651365
area_mean	radius_worst	0.9627461
area_mean	area_worst	0.9592133
area_mean	perimeter_worst	0.9591196
radius_se	area_se	0.9518301
perimeter_mean	area_worst	0.9415498
radius_mean	area_worst	0.9410825
perimeter_se	area_se	0.9376554
concavity_mean	concave points_mean	0.9213910
texture_mean	texture_worst	0.9120446
concave points_mean	concave points_worst	0.9101553

The variables {area\_mean, area\_worst, perimeter\_mean, perimeter\_worst, radius\_mean, radius\_worst} are all mutually correlated. Mathematically, if we consider the equivalence classes of variables that are highly correlated, these six variables would belong to the same equivalence class. Thus, it would be great if we could identify the variable that is the best collective proxy for the other members of this class.

```
# identify largest equivalence class of proxies
corr_df_sub1 <- corr_df %>%
 filter(
    v1 == "area_mean"
                          | v2 == "area_mean"
   | v1 == "area_worst"
                          | v2 == "area_worst"
   | v1 == "perimeter_mean" | v2 == "perimeter_mean"
   | v1 == "perimeter_worst" | v2 == "perimeter_worst"
   | v1 == "radius_mean"
                         | v2 == "radius_mean"
   | v1 == "radius_worst"
                         | v2 == "radius_worst"
 )
# identify variable that is the best proxy for the other ones
group_by(v) %>%
 summarize(
    mean_corr = mean(corr)
   , std_corr = sd(corr)
   , min_corr = min(corr)
 ) %>%
 arrange(-mean_corr) %>%
 knitr::kable()
```

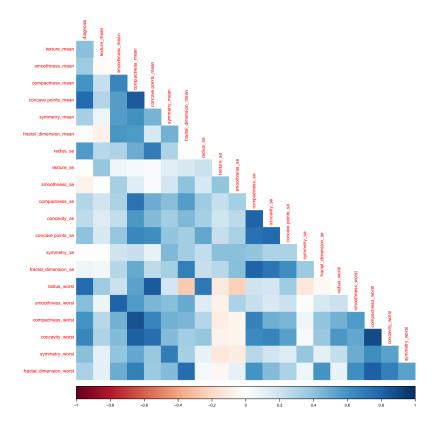

V	mean_corr	std_corr	min_corr
radius_worst	0.9758968	0.0126266	0.9627461
perimeter_worst	0.9731858	0.0133317	0.9591196
perimeter_mean	0.9731550	0.0212630	0.9415498
radius_mean	0.9721941	0.0218701	0.9410825
area_mean	0.9709886	0.0146306	0.9591196
area_worst	0.9606876	0.0198886	0.9410825

The variable radius\_worst is the best collective proxy for the other five variables in its collective equivalence class, so we will retain radius\_worst and discard the rest. Let's look at the remaining variables.

v1	v2	corr
radius_se	perimeter_se	0.9727937
radius_se	area_se	0.9518301
perimeter_se	area_se	0.9376554
concavity_mean	concave points_mean	0.9213910
texture_mean	texture_worst	0.9120446
concave points_mean	concave points_worst	0.9101553

Again, in the spirit of identifying the best representative of each equivalence class, we keep radius\_se, concave.points\_worst, and texture\_mean. In total, we have discarded ten variables.

```
bad_vars <- c(</pre>
    "area_mean", "area_worst", "perimeter_mean", "perimeter_worst", "radius_mean"
    "perimeter_se", "area_se"
    "concave.points_worst", "concavity_mean"
   "texture_worst"
# covariates <-
# bc %>%
# select(-c(diagnosis)) %>%
# select(-bad_vars)
covariates <- bc_trunc</pre>
cor cov <- cor(covariates)</pre>
corrplot::corrplot(cor_cov,
                    method = "color",
                    type = "lower",
                    insig = "blank",
                    diag = FALSE)
```

Better. We'll proceed with these predictors.

fin\_names <- covariates %>% names()

#### Full Model

We want to establish logistic model using all variables in the dataset. We will do this by performing a Newton Raphson optimization in order to find the MLEs of the beta coefficients.

The likelihood function for a logistic model is defined as follows:

$$f(\beta_0, \beta_1, ..., \beta_p) = \sum_{i=1}^n \left( Y_i \left( \beta_0 + \sum_{j=1}^p \beta_j x_{ij} \right) - \log(1 + e^{\left(\beta_0 + \sum_{j=1}^p \beta_j x_{ij}\right)} \right)$$

Let  $\pi_i = \frac{e^{\beta_0 + \sum_{j=1}^p \beta_j x_{ij}}}{1 + e^{\beta_0 + \sum_{j=1}^p \beta_j x_{ij}}}$ . Then, the gradient of this function is defined as follows:

$$\nabla f(\beta_0, \beta_1, ..., \beta_p) = \begin{pmatrix} \sum_{i=1}^n Y_i - \pi_i \\ \sum_{i=1}^n x_{i1} (Y_i - \pi_i) \\ \sum_{i=1}^n x_{i2} (Y_i - \pi_i) \\ \vdots \\ \sum_{i=1}^n x_{ip} (Y_i - \pi_i) \end{pmatrix}$$

Finally, we define the Hessian of this function as follows:

$$\nabla^{2} f(\beta_{0}, \beta_{1}, ..., \beta_{p}) = -\sum_{i=1}^{n} \begin{pmatrix} 1 \\ x_{i1} \\ x_{i2} \\ \vdots \\ x_{ip} \end{pmatrix} (1 \ x_{i1} \ x_{i2} \ ... \ x_{ip}) \pi_{i} (1 - \pi_{i})$$

$$= -\begin{pmatrix} \sum_{i=1}^{n} \pi_{i} (1 - \pi_{i}) & \sum_{i=1}^{n} x_{i1} \pi_{i} (1 - \pi_{i}) & \dots & \sum_{i=1}^{n} x_{ip} \pi_{i} (1 - \pi_{i}) \\ \sum_{i=1}^{n} x_{i1} \pi_{i} (1 - \pi_{i}) & \sum_{i=1}^{n} x_{i1}^{2} \pi_{i} (1 - \pi_{i}) & \dots & \sum_{i=1}^{n} x_{ip} x_{i1} \pi_{i} (1 - \pi_{i}) \\ \sum_{i=1}^{n} x_{i2} \pi_{i} (1 - \pi_{i}) & \sum_{i=1}^{n} x_{i1} x_{i2} \pi_{i} (1 - \pi_{i}) & \dots & \sum_{i=1}^{n} x_{ip} x_{i2} \pi_{i} (1 - \pi_{i}) \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ \sum_{i=1}^{n} x_{ip} \pi_{i} (1 - \pi_{i}) & \sum_{i=1}^{n} x_{i1} x_{ip} \pi_{i} (1 - \pi_{i}) & \dots & \sum_{i=1}^{n} x_{ip}^{2} \pi_{i} (1 - \pi_{i}) \end{pmatrix}$$

$$= (1 \ x_{i1} \ x_{i2} \ ... \ x_{ip}) I(\pi_{i} (1 - \pi_{i})) \begin{pmatrix} 1 \\ x_{i1} \\ x_{i2} \\ \vdots \\ x_{ip} \end{pmatrix}$$

Let's create a function that produces the log-likelihood, gradient vector, and hessian matrix, given a dataset and beta vector:

```
loglike_func <- function(dat, betavec){</pre>
  dat = bc trn
  # x matrix
  dat_temp <-
    dat %>%
    mutate(intercept = 1) %>%
    select(-diagnosis) %>%
    relocate(intercept)
  dat_x <-
    dat_temp %>%
    as.matrix() %>%
    unname()
  # pi vector
  u <- dat_x %*% betavec
  pi \leftarrow exp(u) / (1 + exp(u))
  # loglikelihood
  loglik \leftarrow sum(dat[,1]*u - log(1 + exp(u)))
  #qradient
  grad <- t(dat_x) %*% (dat[,1] - pi)</pre>
  # Hessian
  W <- diag(nrow(pi))</pre>
  diag(W) \leftarrow pi*(1 - pi)
  hess <- -(t(dat_x) %*% W %*% (dat_x))
  return(list(loglik = loglik, grad = grad, hess = hess))
```

```
}
```

Now, let's construct a Newton Raphson algorithm to determine  $\beta_i$  coefficients that maximize the likelihood of the function.

```
NewtonRaphson <- function(dat, start, tol = 1e-8, maxiter = 200){</pre>
  i <- 0
  cur <- start
  stuff <- loglike_func(dat, cur)</pre>
  res \leftarrow c(i = 0, "loglik" = stuff$loglik, "step" = 1, cur)
  prevloglik <- -Inf # to make sure it iterates
  while (i < maxiter && abs(stuff$loglik - prevloglik) > tol) {
    step <- 1
    i <- i + 1
    prevloglik <- stuff$loglik</pre>
    # check negative definite
    eigen_vals <- eigen(stuff$hess)</pre>
    if (max(eigen_vals$values) <= 0 ) { # check neg def, if not change</pre>
      hess <- stuff$hess
    } else { # if it is pos def then need to adjust
      hess <- stuff$hess - (max(eigen_vals$values) + 0.1)*diag(nrow(stuff$hess))
    prev <- cur
    cur <- prev - step*(solve(stuff$hess) %*% stuff$grad)</pre>
    stuff <- loglike_func(dat, cur) # log-lik, gradient, Hessian</pre>
    # step halving
    while (stuff$loglik < prevloglik) {</pre>
      stuff <- loglike_func(dat, prev)</pre>
      step <- step / 2 # this is where half steping happens</pre>
      cur <- prev - step*(solve(stuff$hess) %*% stuff$grad)</pre>
      stuff <- loglike_func(dat, cur)</pre>
    }
    # add current values to results matrix
    res <- rbind(res, c(i, stuff$loglik, step, cur))
  colnames(res) <- c("i", "loglik", "step", "intercept", names(dat[,-1]))</pre>
  return(res)
}
```

#### Splitting Testing and Training Data

Using a function from partition.R, we will split our data into testing and training. We will include only the variables we have identified as being sufficiently uncorrelated.

```
col.num <- which(colnames(bc) %in% fin_names) # get those variables
bc_trunc <- bc[, c(1, col.num)]</pre>
```

```
bc_test_train <- partition(0.8, bc_trunc)

bc_tst <- bc_test_train %>% filter(part_id == "test") %>% select(-part_id)
bc_trn <- bc_test_train %>% filter(part_id == "train") %>% select(-part_id)
```

# Running Newton-Raphson Algorithm

Let's establish a beta vector and run the Newton-Raphson algorithm we've established on the training data.

```
betavec <- c(rep(0.01, ncol(bc_trn))) %>% as.matrix()
nr1 <- NewtonRaphson(bc_trn, betavec)
beta_est <- nr1[nrow(nr1), -c(1:3)] %>% as.vector()
```

# Compare with GLM and GLMNET

```
Let's run GLM.
```

```
glm_fit <- glm(diagnosis~., data = bc_trn, family = "binomial")</pre>
## Warning: glm.fit: fitted probabilities numerically 0 or 1 occurred
result_glm <- summary(glm_fit)</pre>
glm_est <- glm_fit %>%
  broom::tidy() %>%
  select(term, estimate) %>%
  mutate(glm_est = round(estimate, 3)) %>%
  select(-estimate) %>%
  mutate(term = ifelse(term == "(Intercept)", "intercept", term)) %>% pull(glm_est)
Now, let's run GLMNET.
xdat <- bc_trn %>% select(-diagnosis) %>% as.matrix()
glmnet_fit <- glmnet(x = xdat, y = bc_trn$diagnosis, family = "binomial", lambda = 0, thresh = 10^-12)</pre>
glmnet_est <- coef(glmnet_fit) %>% as.vector() %>% round(3)
tibble(
 beta_sub = 0:(length(beta_est) - 1),
 nr_est = round(beta_est, 3),
 glm_est = glm_est,
 glmnet_est = glmnet_est
) %>%
 knitr::kable()
```

$beta\_sub$	nr_est	$glm\_est$	glmnet_est
0	-162.116	-162.116	-162.067
1	1.923	1.923	1.922
